ABSTRACT: Reaction products from the peroxidase-catalyzed oxidation of polyphenols in the presence of cysteine showed a potent activity for reducing metmyoglobin (MetMb) to bright-colored oxymyoglobin (MbO_2). High-performance liquid chromatography (HPLC) purification of the reaction products from catechin, chlorogenic acid, dihydrocaffeic acid, hydroxytyrosol, nordihydroguaiaretic acid, and rosmarinic acid afforded corresponding S-cysteinyl compounds, whose structures were determined by nuclear magnetic resonance (NMR) spectroscopy and mass spectrometry (MS). The isolated cysteinyl polyphenols showed a concentration-dependent reducing activity for MetMb to MbO_2 for initial one hour. However, after one hour, some of them decreased the amount of MbO_2 produced. The effect of the number of cysteinyl sulfur substitutions in polyphenols on both MetMb reduction and MbO_2 maintenance was examined using hydroxytyrosols with different numbers of cysteine substitutions; these hydroxytyrosols were synthesized from hydroxytyrosol and an N-acetylcysteine methyl ester. The hydroxytyrosol derivative that substituted with two N-acetylcysteine esters exhibited the most effective reducing activity without any effect on MbO_2.

KEYWORDS: metmyoglobin reducing activity, cysteinyl polyphenols, peroxidase-catalyzed oxidation, bright meat color preservation
INTRODUCTION

The bright red color of meat is typically an indication of its freshness. The red color is the result of oxymyoglobin (MbO$_2$), which is formed during the blooming process of meat when molecular oxygen reacts with the heme protein, myoglobin. It is well known that myoglobin exists in various redox states, depending on the state of the chelated Fe ion. Myoglobin is rapidly converted to MbO$_2$ in an oxygen atmosphere; however, the produced MbO$_2$ is not very stable and is readily oxidized to a brown-colored metmyoglobin (MetMb). This browning reduces the market value of fresh meat.$^1$

Therefore, the preservation of the bright red color of meat and meat products is very important for the food industry.$^2$

Polyphenols are well-known bioactive constituents of plants and plant-derived foods. They have potent reducing properties, resulting in the inhibition of oxidative deterioration of food. We have previously attempted to utilize such polyphenols to prevent the oxidative browning of MbO$_2$. However, the potent antioxidant polyphenols actually accelerated the oxidation of MbO$_2$ to MetMb.$^3$ This effect could be attributed the pro-oxidant properties of these highly active polyphenols. As an alternative approach to obtain fresh red-colored meat, we attempted to reduce MetMb back to MbO$_2$.$^4$ The results showed that flavonol polyphenols such as quercetin and kaempferol
could partially convert MetMb back to MbO₂, and reduced production of the 
pro-oxidant quinone derivatives was identified as a possible mechanism. However, 
other polyphenols previously reported with a strong reducing potency could not produce 
sufficient amounts of MbO₂. We found that the addition of equimolar amounts of 
cysteine to the polyphenol solution was very effective.⁵ A main reason for this was that 
the pro-oxidant quinones, which were formed in the assay system, were quenched by 
the nucleophilic addition of the cysteiny1 thiol. In another investigation, we also found 
that several cysteine-substituted polyphenols could enhance the antioxidant capacity 
against lipid oxidation.⁶ These results indicated that such cysteine–substituted 
polyphenols exhibited a useful enhancing property for the MetMb reducing and the 
maintenance of MbO₂, which is very important for preserving the color of fresh meat. In 
this investigation, we prepared various cysteine-substituted polyphenols and examined 
their MetMb reducing activity. We also investigated the effect of the number of 
S-cysteiny1-substitutions on the ability of the polyphenols to reduce MetMb using 
hydroxytyrosol.

MATERIALS AND METHODS

Chemicals and instruments. Myoglobin, gentisic acid (purity >98%),
protocatechuic acid (purity >97%), quercetin dihydrate (purity >95%), potassium hexacyanoferrate (III), sodium hydrosulfite, cysteine, and N-butoxycarbonylcysteine were obtained from Nacalai Tesque (Kyoto, Japan). N-Acetyl cysteine (purity >98%), caffeic acid (purity >98%), hydroxytyrosol (purity >98%), myricetin (purity >97%), morin (purity >90% as hydrate), and kaempferol (purity >97% as hydrate) were purchased from Tokyo Kasei (Tokyo, Japan). Catechin (purity >98% as hydrate), rosmarinic acid (purity >97%), chlorogenic acid (purity >95%), nordihydroguaiaretic acid (purity >97%), and dihydrocaffeic acid (purity >98%) were obtained from Sigma-Aldrich (St. Louis, MO). Taxifolin (purity >96%) was obtained from Funakoshi (Tokyo, Japan). Peroxidase (from horseradish) was purchased from Toyobo (Osaka, Japan). All organic solvents (extra pure grade or HPLC grade) were obtained from Nacalai Tesque. Distilled water produced by a water-distilling instrument, SA-2100E (EYELA, Tokyo, Japan), was used for all experiments. NMR spectra were obtained from an ECS-400 spectrometer (JEOL, Tokyo, Japan) or an AVANCE 300N spectrometer (Bruker BioSpin, Yokohama, Japan) using the manufacturer’s pulse sequences for $^1$H, $^{13}$C, HH-COSY, NOESY, HMQC, and HMBC measurements. High-resolution mass spectrometric data were obtained using a XEVO QtofMS spectrometer (Waters Japan, Tokyo, Japan) in ESI mode and determination of each
molecular formula from the MS data was carried out using MassLynx v.4.1 software (Waters Japan). An LC-20AT low-pressure gradient system (Shimadzu, Kyoto, Japan) equipped with an SPD-M20A photodiode array detector (PDA) was employed for analytical HPLC. PDA data were analyzed using LabSolutions ver. 5.51 (Shimadzu). An LC-6AD system (Shimadzu) equipped with a UV-8011 detector (Tosoh, Tokyo, Japan) was used for preparative HPLC.

**Preparation of MetMb.** The MetMb solution was prepared from a stock solution of MbO₂, which was prepared using a method reported previously.⁴ Potassium hexacyanoferrate (III) (2 mg) was added to a solution of MbO₂ (120 µmol/L) in a phosphate buffer (50 mmol/L, pH 7.4, 3 mL) at 23 °C. After gentle stirring for 0.5 min, the solution was desalted three times at 14,000 g for 6 min, at 4 °C, with an Amicon Ultra-0.5, Ultracel-10 ultrafiltration membrane (Merck Millipore, Cork, Ireland) using phosphate buffer. The final residual solution (~ 0.5 mL) was diluted with buffer, yielding 120 µmol/L of the MetMb solution (3 mL). The purity and concentration of the MetMb solution were confirmed using a UVmini 1240 UV/VIS spectrometer (Shimadzu).⁷,⁸

**Coupling Reaction between Polyphenols and Cysteine.** To a straight vial of the solution of each polyphenol in methanol (18 mmol/L, 1 mL), cysteine in water (18
mmol/L, 1 mL), peroxidase in water (60 µmol/L, 20 µL), and H₂O₂ (400 mmol/L, 30 µL) were subsequently added and then the solution was made up to 4 mL with water. The solution was incubated at 25 °C for 8 min to afford oxidized polyphenol solution (4.5 mmol/L based on starting polyphenol concentration). Control experiments were carried out by similar procedure without addition of cysteine to make reference samples.

Measurement of MetMb reduction to MbO₂. Briefly, 50 mmol/L of phosphate buffer (pH 7.4, 250 µL), 120 µmol/L of MetMb (150 µL; in the same buffer), DMSO 10 µL, and the sample solution mentioned above (4.5 mmol/L, 40 µL) were subsequently added to a 96-well microplate. The microplate was then incubated at 37 °C in a Multiskan GO microplate reader (Thermo Fisher Scientific, Yokohama, Japan) for 1 h, and absorbance was measured at 500 and 582 nm. The MbO₂ and MetMb concentrations in the wells were calculated using the following equation:\[^5\]: \[ \text{MbO}_2 (\mu\text{mol/L}) = (89.7 \times A_{582}) - (32.9 \times A_{500}) \] where \(A_{500}\) and \(A_{582}\) refer to absorbance at 500 nm and 582 nm, respectively. The reductive conversion efficiency from MetMb to MbO₂ was expressed as a percentage by calculating the MbO₂ concentration relative to the initial concentration (60 µmol/L) of MetMb.

Purification and Structure Identification of Cysteiny1 Polyphenols.

Preparative HPLC conditions are summarized in a table in supporting information.
section. HR-MS and NMR data of the following synthesized compounds are also summarized in the section.

**Cysteinyl catechins.** To a catechin (50 mg) solution in methanol (4 mL) and water (12 mL) were added cysteine (42 mg), peroxidase (4.6 mg), and H$_2$O$_2$ (0.4 mol/L, 360 µL) with stirring at 25 °C. After several minutes, methanol in the solution was removed *in vacuo* and the resulting solution was purified by preparative HPLC to give 2′-S-cysteinylicatechin (1) and 5′-S-cysteinylicatechin (2) in 16 and 22% yields, respectively.

**Cysteinyl chlorogenic acid.** A chlorogenic acid (50 mg) solution in methanol (3 mL) and water (10 mL), cysteine (103 mg), peroxidase (3.7 mg), and H$_2$O$_2$ (0.4 mol/L, 350 µL) were treated under similar conditions to those of catechin and the obtained reaction mixture was purified by preparative HPLC to give 2″-S-cysteinylchlorogenic acid (3) in 64% yield.

**Cysteinyl dihydrocaffeic acids:** A dihydrocaffeic acid (50 mg) solution in methanol (7 mL) and water (18 mL), cysteine (131 mg), peroxidase (6.6 mg), and H$_2$O$_2$ (0.4 mol/L, 680 µL) were treated under similar conditions to those of catechin and the obtained reaction mixture was purified by preparative HPLC to give 2′,5′-bis(S-cysteinyldihydrocaffeic acid (4) and 5′-S-cysteinylidihydrocaffeic acid (5) in
8% and 65% yields, respectively.

**Cysteiny1 hydroxytyrosols:** A hydroxytyrosol (50 mg) solution in methanol (5 mL) and water (10 mL), cysteine (78 mg), peroxidase (8.1 mg), and H₂O₂ (0.4 mol/L, 350 µL) were treated under similar conditions to those of catechin and the obtained reaction mixture was purified by preparative HPLC to give 2′,5′-bis(S-cysteiny1)hydroxytyrosol (6) and 5′-S-cysteiny1hydroxytyrosol (7) in 5% and 46% yields, respectively.

**Cysteiny1 nordihydroguaiaretic acid:** A nordihydroguaiaretic acid (50 mg) solution in methanol (6 mL) and water (10 mL), cysteine (40 mg), peroxidase (4.4 mg), and H₂O₂ (0.4 mol/L, 450 µL) were treated under similar conditions to those of catechin and the obtained reaction mixture was purified by preparative HPLC to give 5′-S-cysteinylnordihydroguaiaretic acid (8) in 20% yield.

**Cysteiny1 rosmarinic acid:** A rosmarinic acid (50 mg) solution in methanol (3 mL) and water (10 mL), cysteine (101 mg), peroxidase (3.5 mg), and H₂O₂ (0.4 mol/L, 350 µL) were treated under similar conditions to those of catechin and the obtained reaction mixture was purified by preparative HPLC to give 2′,5′(or 5′,6′)-3S-bis[(N-acetyl-O-methy1cysteinyl)hydroxytyrosol (11). To a

Preparation of 5′-S-(N-acetyl-O-methy1cysteinyl)hydroxytyrosol (10) and 2′,5′(or 5′,6′)-S-bis[(N-acetyl-O-methy1cysteinyl)hydroxytyrosol (11).
solution of hydroxytyrosol (400 mg) and N-acetylcysteine methyl ester (551 mg) in acetonitrile (250 mL) was added slowly a fine powder of 2,2-diphenyl-1-picrylhydrazyl (DPPH, 2.1 g) with stirring at 23 °C. The solution was then evaporated in vacuo and filtered after addition of a small amount of the mixed solvent from ethyl acetate and acetone [6:1(v/v)]. The filtrate was subjected to silica gel column chromatography eluted with ethyl acetate-acetone (6:1) and then ethyl acetate-acetone (4:1) to give 10 (176 mg) and 11 (188 mg) in 21% and 15% yields, respectively. The HR-MS and NMR data of 10 and 11 are summarized in supporting information section.

Preparation of 2′,5′,6′- tris[S-(N-acetyl-O-methylcysteinyl)]hydroxytyrosol (12) To a solution of di-N-acetyl-O-methylcysteine substituted hydroxytyrosol (11, 90 mg) and N-acetylcysteine methyl ester (40 mg) in acetone (50 mL) was added a fine powder of DPPH (140 mg) with stirring at 23 °C. After stirring for several minutes, the solution was evaporated and subjected to column chromatography on silica gel (Cosmosil 75-SR-II-PREP, Nacalai) eluted with ethyl acetate-acetone (1:2) to give 12 (60 mg) in 50% yield. The HR-MS and NMR data of 12 are summarized in supporting information section.

RESULTS AND DISCUSSION
Metmyoglobin-reducing activity of peroxide-catalyzed reaction products from polyphenols and cysteine. For the coupling of polyphenols with cysteine, we found that peroxidase-catalyzed oxidation gave the best result. Other methods that employ chemical reagents for this purpose either oxidized the cysteine first or required time-consuming follow-up to remove the reacted reagents. The MetMb-reducing activity of 40 µL of the peroxidase reaction solutions, which were prepared from equimolar concentrations of polyphenol and cysteine, was measured using a freshly prepared MetMb solution (60 µmol/L). The data, which are summarized in Figure 1, show that most reaction products exhibited remarkable MetMb-reducing activity, whereas the peroxidase-oxidized polyphenols without cysteine did not show such high activity, except for the products from kaempferol and morin. Among the polyphenols examined, hydroxytyrosol, catechin, and caffeic acid showed the highest efficiency, followed by kaempferol, morin, taxifolin, rosmarinic acid, nordihydroguaiaretic acid. We had previously reported a high-MetMb reducing activity of polyphenols in the presence of cysteine suggesting that cysteiny1 polyphenols produced in the solutions might play a role in MetMb-reducing activity. We therefore isolated cysteiny1 polyphenols from the reaction mixtures and measured their ability to convert MetMb reductively to MbO₂.
**Isolation and structure identification of cysteinyl polyphenols.** From the catechin reaction, two cysteinyl catechins (1 and 2) were detected using HPLC analysis and these were isolated using a preparative HPLC technique as described in the experimental section. High-resolution MS (HR-MS) of 1 and 2 revealed that they had the same molecular formula (C_{18}H_{19}NO_{3}S), indicating that both were isomers of mono-cysteine-substituted catechins. The substituted position was deduced by NMR data. The \(^1\)H NMR data of 1 showed a coupling constant that signified ortho-related protons in the B-ring, indicating that the cysteine was substituted at the 2″-position. C-H long-range correlations in HMBC of 1 were observed between C2′ and H2, C6′ and H2, and C2′ and H2″, indicating that the substitution at position 2′ was through cysteinyl sulfur linkage. 1 was therefore determined to be 2′-S-cysteinylcatechin (Figure 2). For the structure of 2, a meta-related coupling constant (1.8 Hz) was observed between H2′ and H6′ of the \(^1\)H NMR data of B-ring. 2 was therefore determined to be 5′-S-cysteinylcatechin (Figure 2).

The peroxidase-catalyzed reaction of chlorogenic acid yielded a major coupling product (3), which had the molecular formula: C_{19}H_{23}NO_{11}S as derived from HR-MS data. The position of the substituted cysteine was determined from \(^1\)H NMR data, which showed two ortho-coupling protons in a caffeate moiety. The structure of 3 was
therefore determined to be 2'-S-cysteinylchlorogenic acid (Figure 2).

Dihydrocaffeic acid gave major two coupling products (4 and 5) by the peroxidase-catalyzed reaction. These products were estimated to be di- and mono-cysteinyl dihydrocaffeic acid from the HR-MS data (m/z 419.0572 [M-H]⁻ and 300.0527 [M-H]⁻, respectively). The substituted cysteine in mono-cysteinyl dihydrocaffeic acid (5) was estimated to occupy the 5'-position, because the meta-related coupling constant (2.4 Hz) was clearly observed in doublet signals of H2' and H6'. 5 was therefore determined to be 5'-S-cysteinyl dihydrocaffeic acid. For the di-cysteine-substituted dihydrocaffeic acid (4), the ¹H NMR data were too complex to allow complete elucidation of the structure. An aromatic proton signal was observed at 7.01 ppm as a singlet and NOE was observed from the aromatic proton to H2 and H3 of the cysteine part. These data indicated that the positions of the two substituted cysteines were either 2' and 5' or 5' and 6'. Therefore, 4 was a di-cysteine-substituted dihydrocaffeic acid such as 2',5'-bis(S-cysteinyl)dihydrocaffeic acid or 5',6'-bis(S-cysteinyl)dihydrocaffeic acid (Figure 2).

A peroxidase-catalyzed reaction of hydroxytyrosol in the presence of cysteine yielded two products (6 and 7). HR-ESIMS analysis of both products revealed that 6 and 7 were di-cysteine-substituted hydroxytyrosol and mono-cysteine-substituted
hydroxytyrosol, respectively. The $^1$H-NMR spectrum of 6 was very complex except for the observation of a singlet aromatic proton at 7.03 ppm. We synthesized bis[S-(N-butoxycarbonylcysteinyl)]hydroxytyrosol from hydroxytyrosol and N-butoxycarbonylcysteine. In the compound, clear NOE between the aromatic proton and H3 of the cysteine part was observed, indicating that the substituted positions of the cysteines were either 2’ and 5’ or 5’ and 6’. Acid treatment of the di-(N-butoxycarbonyl)cysteinyl hydroxytyrosol gave 6. Therefore, 6 should be 2’,5’ (or 5’,6’)-bis(S-cysteinyl)hydroxytyrosol. Mono-cysteine substituted hydroxytyrosol (7) was also analyzed by NMR. Two meta-coupled aromatic protons were clearly observed in the $^1$H NMR of 7, revealing that 7 was 5’-S-cysteinylnhydroxytyrosol (Figure 2).

Nordihydroguaiaretic acid, a potent antioxidant of creosote bush, also gave a coupling product 8 from the peroxidase reaction. The substituted position of the cysteine was determined to be at the 5’-position of one of the aromatic rings, which was revealed from the meta-related coupling constant between H2’ and H6’ in the $^1$H NMR of 8. Thus, 8 was determined to be 5’-S-cysteinylnordihydroguaiaretic acid (Figure 2).

Rosmarinic acid, a labietae polyphenol, also yielded mono-cysteinylnrosmarinic acid (9) as a peroxidase-catalyzed reaction product. Rosmarinic acid has two tri-substituted benzene rings, however, the $^1$H NMR data of 9 showed the existence of a
four-substituted benzene ring possessing two protons with ortho coupling constant (8.4 Hz). One of the protons of the benzene ring was relatively low-field shifted. Therefore, the substituted cysteine was determined to be at the 2-position of the benzene ring of a caffeoyl moiety of rosmarinic acid. Thus, 9 was 2″-S-cysteylnrosmarinic acid (Figure 2).

**Metmyoglobin-reducing activity of cysteinyl polyphenols.** Figure 3 shows the percent ratio of MbO$_2$ produced in the reducing reaction of 60 µmol of MetMb by 60 – 600 µmol of cysteinyl polyphenols. All cysteinyl polyphenols examined showed remarkable and concentration-dependent reducing activity to MetMb for the first hour of the reaction. A decrease of MbO$_2$ was observed in the reaction with cysteinyl polyphenols 5, 7, 8, and 9 after one hour. It should be noted that cysteinyl nordihydroguaiaretic acid (8) and cysteinyl rosmarinic acid (9) have two catechol structures and one of them remains in the intact form. We have reported that highly antioxidative polyphenols, most of which have the same catechol structure, enhance the oxidation of MbO$_2$ in part owing to their pro-oxidant property. Therefore, the intact catechol structures of 8 and 9 should enhance the oxidative decrease of the initially produced MbO$_2$. Cysteinyl polyphenols 5 (mono-cysteinyl dihydrocaffeic acid) and 7 (mono-cysteinyl hydroxytyrosol) have very similar structures. Although our previous
results showed that a mono-sulfur substitution reduces the pro-oxidant properties of highly reactive polyphenols\textsuperscript{4,5} it is possible that a mono-cysteine-substituted dihydrocaffeic acid and hydroxytyrosol still have potent reactivity.\textsuperscript{10} These polyphenols have a catechol structure with no conjugated electron-withdrawal groups, which have high reactivity and enhance both antioxidant and pro-oxidant activities. Therefore, the remaining pro-oxidative properties might exhibit oxidation of MbO\textsubscript{2} at the end of the one-hour reaction. Noticeably, di-cysteine-substituted dihydrocaffeic acid (4) and hydroxytyrosol (6) did not show obvious pro-oxidant activity, which supports the idea that multi-sulfur substitution might reduce the pro-oxidant activity to MbO\textsubscript{2}, even in the presence of highly reactive polyphenols.

The effect of the number of sulfur substitutions in polyphenols on metmyoglobin reduction and oxymyoglobin oxidation. Our previous results showed that in cysteinyl dihydrocaffeic acids and hydroxytyrosols, the number of sulfur substitutions have different effects and up to three substituents can be made to the benzene region. The question then arose as to how many cysteine substitutions would exhibit the best results in the terms of MetMb reduction and MbO\textsubscript{2} production and retention. We attempted to synthesize tri-cysteine-substituted hydroxytyrosol, but were unsuccessful using the peroxide-catalyzed method as well as other chemical oxidation
reagents. The reason for the failure seemed to be faster oxidation of the thiol part of the cysteine. We have reported that oxidation of the thiol part of the cysteine can be prevented by protection of both α-amino and carboxylic groups. Using N-acetylcysteine methyl ester (NAC-OCH$_3$) as such a protectant, we prepared multi-sulfur-substituted hydroxytyrosols. The oxidative coupling of hydroxytyrosol with NAC-OCH$_3$ was performed in anhydrous acetonitrile using DPPH (2,2-diphenyl-1-picrylhydrazyl) as an oxidation reagent. The reaction of hydroxytyrosol with 4 equivalents of DPPH in the presence of equimolar NAC-OCH$_3$ yielded mono-substituted hydroxytyrosol (10) and di-substituted hydroxytyrosol (11) in 21% and 15% yields, respectively. Additional DPPH oxidation of 11 with NAC-OCH$_3$ gave a tri-substituted hydroxytyrosol (12) in 50% yield (Figure 4). The MetMb-reducing activities of 10, 11, and 12 were measured and the data are illustrated in Figure 5. The effects of NAC-substituted hydroxytyrosols (10—12) and intact hydroxytyrosol on MbO$_2$ are presented in Figure 6. Hydroxytyrosol and mono-cysteinyl derivative 10 showed no MetMb-reducing activity, whereas the di-cysteinyl derivative 11 and the tri-cysteinyl derivative 12 showed strong and concentration-dependent reducing activity. In particular, a higher reducing efficiency was observed in 11 (Figure 5), revealing that the di-sulfur-substituted compounds were the most effective at the reducing MetMb.
contrast, an additional substitution weakened the reducing activity of the di-substituted hydroxytyrosol. It should be noted that the reducing efficiency of the di-substituted hydroxytyrosol (11) reached almost a 100% for 3 h at 37 °C at a concentration of 600 µmol/L versus 60 µmol/L of myoglobin. However, mono-substituted hydroxytyrosol (10)-induced enhancement of MbO₂ oxidation was similar to that of hydroxytyrosol, while di- and tri-substituted hydroxytyrosols showed negligible enhancement (Figure 6).

We have previously reported that the antioxidant capacity of a dihydorcaffeic ester was enhanced in the presence of a cysteine derivative. The antioxidation of dihydorcaffeic ester in the presence of a cysteine derivative in the production of mono-, di-, and tri-cysteinyl dihydorcaffeates. Furthermore, these mono- and di-substituted dihydorcaffeates mainly caused an increase in the length of the antioxidation period of dihydorcaffeate. Different reactivity to a peroxy radical was also observed among these cysteinyl dihydorcaffeates. These results clarified that the substitution of cysteine, and specifically a sulfur substitution, modulated the redox abilities of the original polyphenols. In the cysteinyl hydroxytyrosols, di-cysteine-substituted hydroxytyrosol (11) showed the most efficient reducing activity for MetMb and no prooxidant effect on MbO₂. It is well known that hydroxytyrosol is an antioxidant present in olives and is also the antioxidant part of oleuropein which is the main polyphenol not only in young
olive fruits\textsuperscript{13} but also in olive leaves.\textsuperscript{14} A series of investigations, including the current
study,\textsuperscript{3-5} have demonstrated that potent active polyphenols could be used for
preservation of fresh meat color in the presence of cysteine or related thiol compounds.
We have also shown that a simple peroxidase-catalyzed reaction can be used for the
modification of polyphenols to effectively reduce brown-colored MetMb. This simple
method, which requires catalytic amount of enzyme and minimum amounts of cysteine
and hydrogen peroxide, is applicable to advanced utilization of the raw extracts of
polyphenol-rich plant resources such as olive leaves, because the reaction solution may
be used directly for fresh meat color preservation.
